Objectives: The aim of the study was to reveal demographic data, laboratory and vein duplex findings in patients hospitalized for venous thrombosis and thromboembolism. Specific interest was focused on usual laboratory findings such as D-dimer, coagulation cascade parameters and thrombophilia investigation and its relationship with the severity of deep vein thrombosis (DVT). Risk factors such as cardiovascular diseases, malignancy, trauma, metabolic parameters and other well known data were analyzed. The increasing incidence of venous thrombosis in ageing population has changed the priority list and the importance of usual risk factors.

Patients and Methods: The study included all patients with clinical suspicion for DVT and/or pulmonary embolism (PE), treated in the University Hospital Centre Zagreb through the period of 52 months. Three hundred twenty-four patients with venous thrombosis and/or pulmonary embolism were analyzed. Antropometric, biochemical and lipid parameters, hypercoagulability factors, malignancy, trauma or surgery, cardiovascular disease, DVT family history, previous DVT or PE were evaluated. Patients were grouped according to the vein thrombosis location. Diagnosis of DVT was done with duplex scan. PE was diagnosed on MSCT pulmonary angiography or lung ventilation-perfusion scintigraphy.

Results: DVT was diagnosed in 264 (81.5%) and PE in 80 patients (24.7%). Only 46 patients suffering from PE had evidence of venous thrombosis on the limb duplex scan. The femoral and popliteal veins were the most common sites of thrombi. The frequency of patients older than 55 years was 68.2%. Similar incidence was found in both sexes. The evidence of cardiovascular disease was the most frequent risk factor (47.8%). Malignancy was found in 62 patients (19.2%). The incidence of previous surgery or any trauma was 17%. Thrombophilia as the only risk for venous thrombosis was revealed in 63 patients. Proximal DVT was most extensive in the older age group (P<0.0001). D-dimer values had significant positive correlation with thrombosis severity (P<0.0001).

Conclusion: Cardiovascular disease had the highest incidence in population suffering from venous thromboembolism. This finding emphasized the importance of careful preventive strategies in patients with cardiovascular disease. In clinical settings, higher levels of D-dimer could implicate proximal deep venous thrombosis.
