Introduction: Myxomas are the most common benign primary cardiac tumors with the majority (85%) located in the left atrium. Clinical manifestations are diverse and are consequence of embolic phenomena, intracardiac obstruction or constitutional symptoms. Early diagnosis, most perplexing in a patient with constitutional symptoms, remains an important challenge for the clinician, as they have an excellent prognosis following surgical excision, preventing complications and improving quality of life.1-3

Case report: We report a case of a 75-year-old female presented with fatigue and weight loss. Symptoms were first attributed to her history of hyperthyroidism. After series of normal hormonal and thyroid ultrasound findings she was referred to gastroenterologist for the evaluation of microcytic anemia (Hb 101g/L). Even though results of fecal occult blood testing were negative, esophagogastroduodenoscopy and colonoscopy were performed subsequently having sent our patient to hematologist for further examinations regarding anemia. After a year of anemia assessment she underwent transthoracic echocardiography which demonstrated an intraatrial mass. Immediately hospitalized, transesophageal echocardiography (Figure 1, Figure 2) and magnetic resonance imaging (Figure 3) were performed. Features of the mass were consistent with notably large myxoma, occupying nearly the entire left atrium and prolapsing across the mitral valve during diastole. Coronary angiography showed no obstructive coronary artery disease. Our patient underwent urgent cardiothoracic surgery with successful excision of atrial mass attached to the interatrial septum, pathologically confirmed myxoma (Figure 4). Cardiac rehabilitation followed immediately after discharge, with normalization of hemoglobin levels.
Conclusion: Diagnosis of atrial myxomas is often challenging due to their asymptomatic nature or nonspecific symptoms presentation. Constitutional symptoms, like weight loss and fatigue and associated laboratory findings (elevated sedimentation rate and anemia) are explained as a result of interleukin-6 production by cardiac myxoma cells. Although histopathologically benign, complications due to their position and embolization can be fatal. Therefore, prompt complete surgical excision after diagnosis, regardless of whether the patient is symptomatic, is strongly recommended. The present case summons the significance of considering atrial myxoma while investigating a patient presenting with constitutional symptoms and persistent unexplained anemia. Early suspicion supported by echocardiogram may facilitate the diagnosis.
